Report No 175
ACKNOWLEDGMENTS

The report authors wish to acknowledge the assistance of Beth Sachs and Blair Hamilton of the Memphremagog Group in preparing the index lists in Chapter 3. Also, we would like to thank the representatives of Subtask A who completed the survey forms and reviewed the final report and Sheila Blum and Jean Mewshaw of International Planning Associates for their editorial assistance.
INTRODUCTION TO THE IEA SOLAR HEATING AND COOLING PROGRAMME

BACKGROUND

International Energy Agency was formed in November 1974 to establish cooperation among a number of industrialized countries in the vital area of energy policy. It is an autonomous body within the framework of the Organization for Economic Cooperation and Development (OECD). Twenty-one countries are presently members, with the Commission of the European Communities also participating in the work of the IEA under a special arrangement.

One element of the IEA's programme involves cooperation in the research and development of alternative energy resources in order to reduce excessive dependence on oil. A number of new and improved energy technologies which have the potential of making significant contributions to global energy needs were identified for collaborative efforts. The IEA Committee on Energy Research and Development (CRD), supported by a small Secretariat staff is the focus of IEA RD&D activities. Four Working Parties (in Conservation, Fossil Fuels, Renewable Energy, and Fusion) are charged with identifying new areas for cooperation and advising the CRD on policy matters in their respective technology areas.

SOLAR HEATING & COOLING AGREEMENT

Solar Heating and Cooling was one of the technologies selected for joint activities. During 1976-77, specific projects were identified in key areas of this field and a formal Implementing Agreement drawn up. The Agreement covers the obligations and rights of the Participants and outlines the scope of each project or "task" in annexes to the document. There are now eighteen signatories to the Agreement:

- Australia
- Austria
- Belgium
- Canada
- Denmark
- Commission of the European Communities
- Federal Republic of Germany
- Greece
- Italy
- Japan
- Netherlands
- New Zealand
- Norway
- Spain
- Sweden
- Switzerland
- United Kingdom
- United States
The overall programme is managed by an Executive Committee, while the management of the individual tasks is the responsibility of Operating Agents. The tasks of the IEA Solar Heating and Cooling Programme, their respective Operating Agents, and current status (ongoing or completed) are as follows:

Task I  Investigation of the Performance of Solar Heating and Cooling Systems - Technical University of Denmark (Completed).

Task II  Coordination of Research and Development on Solar Heating and Cooling - Solar Research Laboratory - GIRIN, Japan (Completed).

Task III  Performance Testing of Solar Collectors - University College, Cardiff, U.K. (ongoing)

Task V  Use of Existing Meteorological Information for Solar Energy Application - Swedish Meteorological and Hydrological Institute (Completed).

Task VII  Central Solar Heating Plants with Seasonal Storage - Swedish Council for Building Research (Ongoing).

Task IX  Solar Radiation and Pyranometry Studies - Canadian Climate Centre (Ongoing).

Task X  Materials Research & Testing - Solar Research Laboratory, GIRIN, Japan (Ongoing).
TASK VIII - PASSIVE AND HYBRID SOLAR LOW ENERGY BUILDINGS

The Participants in Task VIII are involved in collaborative research to study the design integration issues associated with using passive and hybrid solar and energy conservation techniques in new residential buildings. The overall objective of Task VIII is to accelerate the development and use of passive and hybrid heated and cooled low energy buildings in the Participants' countries. The results will be an improved understanding of the design and performance of buildings using active and passive solar and energy conservation techniques, their interaction and effective combination in various climatic regions. The results will also verify that passive and hybrid solar low energy buildings can substantially reduce the building load and consumption of non-renewable energy over that of conventional buildings while maintaining acceptable levels of year-round comfort. The Subtasks of this project are:

O. Technology Baseline Definition
A. Performance Measurement and Analysis
B. Modeling and Simulation
C. Design Methods
D. Building Design, Construction and Evaluation

The Participants in this Task are: Austria, Belgium, Canada, Denmark, Federal Republic of Germany, Italy, The Netherlands, New Zealand, Norway, Spain, Sweden, Switzerland, United States and United Kingdom. Michael J. Holtz, A.I.A., Architectural Energy Corporation, serves as Operating Agent on behalf of the U.S. Department of Energy.

This report documents work carried out under Subtask A of this Task.

1. EXECUTIVE SUMMARY

This document presents the results of a survey of monitored passive and hybrid solar low energy residential buildings conducted within IEA countries during the period from autumn 1983 to spring 1985. The survey was undertaken as part of Subtask A, Performance Measurement and Analysis, of Task VIII, Passive and Hybrid Solar Low Energy Buildings of the IEA Solar Heating and Cooling Programme. One of the objectives of this Subtask is to report on the availability of data from monitored passive and hybrid solar low energy residential buildings in the member countries. The intent is to identify sources of high quality performance data for purposes of simulation and design tool evaluation, passive and hybrid system performance characterization and policy formulation. The major part of the report consists of building description forms which briefly describe the buildings, summarize performance, list available data and identify reference sources for further information. More detailed performance data is provided for 60 of the buildings. To assist the reader in findings projects of particular interest, an indexing system has been generated, using 16 different entries from the forms.

The objectives of the survey were:

1. To determine the availability of data from monitored projects in the IEA Task VIII member countries;

2. To identify data needs;

3. To make designers, builders and researchers aware of available data; and

4. To document and assess the performance of the surveyed buildings in order to make comparisons of passive/hybrid system performance in various climates.

The survey forms were generated and distributed to the participating countries of Task VIII. One survey form was used to identify sources of performance data and the other form to briefly report the performance of selected projects. The survey forms are included as Appendix A to this report.
The survey identified 181 monitored passive and hybrid solar residential buildings in seven countries for which performance data are available. Information from the survey forms was used to prepare the building description forms in Chapter 4 which describe the building, briefly summarize performance, list available data and identify reference sources for further information. Key information from these forms was reorganized into a set of index lists, presented in Chapter 3, which assist the reader in identifying the performance evaluation sites and data sets which may be of particular interest.

More detailed system and building descriptions and building performance information were included for 60 of the projects. These performance data forms are presented in Chapter 5 and provide illustrations and performance assessments for specific system types in the different climates.

Of the 181 reported projects, 148 are from the U.S. This clearly indicates a greater emphasis on performance monitoring in the U.S. in the past 5 years. However, the number of monitored European and New Zealand sites is increasing and a larger data base of quality data will soon be available from those countries.

The categories of passive heating systems in the surveyed projects and their distribution is shown in Figure 1.1.

As would be expected, the greatest number of monitored projects are for direct gain, mass wall and sunspace heating systems, the most popular passive system types. Limited performance data exists for water wall, hybrid, roof pond and other innovative systems, reflecting the current limited use and interest in these systems by designers and researchers.

Categorization of the monitored sites by climate variables is useful in assessing data availability and data needs. Figures 1.2 and 1.3 show the distribution of projects plotted against annual global solar radiation and Heating Degree Days and Cooling Degree Days, respectively.
Figure 1.1 Distribution of Sites by Passive Heating System Type (absolute number, percentage).
Figure 1.2 Distribution of Projects by Heating Degree Days vs. Annual Global Solar Radiation.
Figure 1.3 Distribution of Projects by Cooling Degree Days vs. Annual Global Solar Radiation.
Conclusions

A detailed assessment of the survey results was not performed. However, a review of the monitored projects reported in the surveys leads to the following general conclusions:

1. The majority of reported projects are from the United States. A clear need exists for additional monitored data from European climates.

2. The majority of the reported projects are for the most common passive heating system types - direct gain, thermal storage walls and sun-space.

3. An insufficient number of hybrid solar heating systems are reported to allow the performance comparison of this system type with either totally active or passive systems.

4. Little data are reported on the performance of roof ponds or water walls.

5. Data quality in general appears to be high. However, usefulness for purposes of simulation validation, design tool evaluation or system performance comparison can only be assessed on a case-by-case basis.

6. A need exists for the development and use of a consistent performance evaluation methodology to allow comparison of data among various countries.

The present survey has created an overview of available performance data on passive and hybrid solar low energy buildings in the IEA Task VIII member countries. This overview provides important guidance of the planning of future monitoring projects in this area.
2. INTRODUCTION

The absence of thermal performance data from monitored passive and hybrid solar residential buildings used to be a major obstacle to designers, builders, researchers, analysts and policy-makers seeking to determine the value of these energy saving concepts. Within the last five years, however, the number, location and types of passive and hybrid solar residential buildings monitored within IEA countries has grown dramatically. The number of monitored passive and hybrid solar buildings is currently estimated to be over 200. The issue has now become how to make data from selected monitored buildings available so that it can be further analyzed and used by designers, builders and researchers.

The purpose of this publication is to present and index sources of monitored performance data for passive and hybrid solar residential buildings in the countries participating in Subtask "A" of IEA Task VIII. Only buildings which have undergone six months of monitoring critical performance variables have been included in this report. Also, the quality of the data had to be high, and the monitored results fully documented with available data sets.

The survey information is presented in three parts. The first part, Chapter 3, is an index of 16 lists that tabulate the 181 buildings according to various characteristics - heating degree days, type of construction, auxiliary system type, and so on. The second part, Chapter 4, is a series of single page forms that describe each building, briefly summarize performance, list available data and identify reference sources for further information. The third part, Chapter 5, presents drawings and more detailed information on 60 of the monitored buildings.

The intended process for using this report is as follows:

1. Carefully define your requirements for the type of data needed, such as location, passive system type, building type, and so on.

2. Review the 16 lists in Chapter 3 to select the appropriate indices.

3. Review Chapters 4 and 5 to identify candidate monitored projects.
4. Rank the candidate monitored projects in descending order of usefulness relative to your data needs.

5. Contact the individual or organization identified as the project contact on the Project Summary Forms in Chapter 4 to obtain additional information on the monitored project and the availability of documentation.

6. Make arrangements to obtain the data and all necessary project documentation.

Data acquisition is an extremely difficult, time-consuming and expensive activity. Yet monitored data is indispensable for model validation, design tool evaluation and building performance evaluation/comparison. This report is intended to bring possible sources of quality monitored data to the attention of those requiring such information. It is hoped that it will facilitate the acquisition of valuable measured performance information, saving time, money and avoiding unnecessary project duplication.
3. INDEX LISTS

This chapter contains 16 lists to assist in identifying particular performance evaluation sites and data sets which may be of interest. The following tabulations of site characteristics are included in the following pages:

3.1 List of Sites by Location
3.2 List of Sites by Level of Monitoring
3.3 List of Sites by Heating Degree Days
3.4 List of Sites by Cooling Degree Days
3.5 List of Sites by Global Solar Radiation
3.6 List of Sites by Aperture/Floor Area Ratio
3.7 List of Sites by Heated Floor Area
3.8 List of Sites by Total Heat Loss Coefficient
3.9 List of Sites by Passive Heating System Type
3.10 List of Sites by Passive Cooling System Type
3.11 List of Sites by Other Passive Components
3.12 List of Sites by Thermal Storage Materials
3.13 List of Sites by Type of Construction
3.14 List of Sites by Auxiliary Fuel Type
3.15 List of Sites by Auxiliary System Type
3.16 List of Sites by Building Type

To assist the reader in using and understanding the index lists, the following explanatory notes are provided.

1. Each site in the index lists has been assigned a site code. The first two characters of the code represent the country in which the site is located, i.e., BE = Belgium and CD = Canada. The last two characters of the code represent the site number, i.e., BE-02 is the second site in Belgium. Because there are so many sites in the U.S., an abbreviation for the state is also included. For example, US/AZ-01 is the first U.S. site in Arizona. The single-page data sheets in Chapter 4 are arranged in order of these site codes.
2. The "levels of monitoring" referred to in this report are based on the categories used in the U.S. (1). They are defined as follows:

Level "A" typically over 100 sensors; hourly data; continuously measured infiltration; measured properties of materials.

Level "A-" typically over 100 sensors; hourly data; one-time or intermittent infiltration measurement; assumed properties of materials.

Level "B+" typically over 20 sensors; at least some hourly data; one-time measurements; monthly energy balances; measured indoor and outdoor environment.

Level "B" typically over 20 sensors; one-time measurements; monthly energy balances; measured indoor and outdoor environment.

Level "B-" similar to Level B but lacking full information to determine monthly energy balances.

3. In any list where a single building has multiple characteristics by which it might be listed, there are duplicate listings for the site, one under each characteristic.

4. Not all sites are found on all of the 16 lists. For any site this may either be because the particular characteristic does not apply to the site or because information on that characteristic for the site was not available.

4. BUILDING AND SYSTEM DESCRIPTION FORMS

This chapter contains the building system description forms for each of the monitored passive and hybrid solar projects. The information for these forms was obtained from the original survey completed by the IEA Task VIII participants. Information not listed on the form was not received from the respondents. The building system description form is organized into nine categories:

1. Name
2. Location
3. Climate
4. Building Description
5. Passive Solar System
6. Monitoring
7. Performance
8. Reports
9. Notes

The language of the available reports is indicated in parentheses after the bibliographic reference. All United States reports are in English.
SITE CODE: BE-01

SITE NAME: Nandrin Direct Gain/Sunspace
LOCATION: Nandrin, Belgium

CLIMATE
Heating Degree Days: 2100
Cooling Degree Days:
Global Solar Radiation: 975 kWh/m²

BUILDING DESCRIPTION
Building Type: single detached
Construction Type: masonry
Ground Coupling: slab on grade
Number of Stories: 1
Auxiliary Fuel(s): wood; liquid
Auxiliary System(s): woodstove; forced air-furnace
Number of Occupants: 4
Conditioned Floor Area: 165 m²
Aperture/Floor Area Ratio: 0.68
Global Heat Loss Coefficient: 339 W/degree K

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): direct gain; sunspace
Passive Cooling System Type(s): ventilation
Thermal Storage Material: masonry walls and floor
Other Passive Component(s):

MONITORING
Level of Monitoring: B+
Monitoring Period: 12/82 to 5/83
Format of Data: computer tape
Quality of Data:

PERFORMANCE

REPORTS
Concours Habitat Thermique, rapport de synthesese.
Available from: Region Wallonne-Cabinet du Ministre Busquin, rue du Commerce, 31, 1040 Bruxelles, Belgique. (French)

NOTES
Most auxiliary heat provided by woodstove. Sunspace is used primarily for horticulture.
SITE CODE: BE-02

SITE NAME: Chaumont Gistoux Solar House
LOCATION: Chaumont-Gistoux, Belgium

CLIMATE
Heating Degree Days: 2100
Cooling Degree Days:
Global Solar Radiation: 975 kWh/m²

BUILDING DESCRIPTION
Building Type: single detached
Construction Type: masonry
Ground Coupling: basement
Number of Stories: 2.5
Auxiliary Fuel(s): liquid fuel
Auxiliary System(s): hydronic
Number of Occupants: 3
Conditioned Floor Area: 240 m²
Aperture/Floor Area Ratio: 0.23
Global Heat Loss Coefficient: 148 W/degree K

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): direct gain; sunspace
Passive Cooling System Type(s): ventilation
Thermal Storage Material: masonry walls and floor
Other Passive Component(s):

MONITORING
Level of Monitoring: B+
Monitoring Period: 12/82 to 5/83
Format of Data: computer tape
Quality of Data:

PERFORMANCE

REPORTS
Concours Habitat Thermique, rapport de synthese.
Available from: Region Walloon-Cabinet du Ministre Busquin, rue du Commerce, 31, 1040 Bruxelles, Belgique. (French)

NOTES
House also has active solar system with 52 m² flat plate collectors and 30 cubic meters of water storage. Dominant passive system is sunspace with 33m² aperture and 16m² floor area.
SITE CODE: BE-03

SITE NAME: Rosieres Solar House  CONTACT: C.R.A.
LOCATION: Rosieres, Belgium  ADDRESS: Batiment Vinci

CLIMATE
Heating Degree Days: 2100
Cooling Degree Days:
Global Solar Radiation: 975 kWh/m²

BUILDING DESCRIPTION
Building Type: single detached
Construction Type: masonry
Ground Coupling: slab on grade
Number of Stories: 3
Auxiliary Fuel(s): gas; wood
Auxiliary System(s): hydronic; woodstove
Number of Occupants: 4
Conditioned Floor Area: 168 m²
Aperture/Floor Area Ratio: 0.31
Global Heat Loss Coefficient: 309 W/degree K

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): direct gain; sunspace; trombe wall
Passive Cooling System Type(s): 
Thermal Storage Material: slab on grade; masonry walls
Other Passive Component(s):

MONITORING
Level of Monitoring: B+
Monitoring Period: 12/82 to 5/83
Format of Data: computer tape
Quality of Data:

PERFORMANCE

REPORTS
Concours Habitat Thermique, rapport de synthese.
Available from: Region Wallonne-Cabinet du Ministre Busquin, rue du Commerce, 31, 1040 Bruxelles, Belgique. (French)

NOTES
The sunspace has a 37 m² aperture and a 20 m² floor area. The Trombe wall has a 14m² collection area and is 40 cm thick.
SITE CODE:  CD-01

SITE NAME: NRC Passive Solar Test Fac.  CONTACT: Sherif Barakat
LOCATION: Ottawa, Canada  ADDRESS: Thermal Performance Section
CLIMATE
Heating Degree Days: 4674  Div. of Bldg. Research
Cooling Degree Days: 242  NRCC
Global Solar Radiation: 1328 kWh/m²  Ottawa, Canada K1A OR6

BUILDING DESCRIPTION
Building Type: detached test buildings
Construction Type: wood frame
Ground Coupling: basement
Number of Stories: 1
Auxiliary Fuel(s): electric
Auxiliary System(s): baseboard heaters
Number of Occupants: 0
Conditioned Floor Area: 28 m²
Aperture/Floor Area Ratio: 0.09
Global Heat Loss Coefficient: 26 W/degree K

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): direct gain; sunspace
Passive Cooling System Type(s): ventilation
Thermal Storage Material: varies
Other Passive Component(s): 

MONITORING
Level of Monitoring: A-
Monitoring Period: 11/80 to 4/82
Format of Data: computer tape
Quality of Data: 

PERFORMANCE

REPORTS
NRC Passive Solar Test Facility, Performance Summary. Available from: S. Barakat, Thermal Performance Section, Division of Bldg. Research, NRCC, Ottawa, Canada K1A OR6. (English)

NOTES
Facility consists of four 2-zone test units and 4 single-room units. Data has been collected for different types and amounts of storage for both direct gain and sunspace configurations.
SITE CODE: CD-02

SITE NAME: Alberta Home Heat Res. Fac.  CONTACT: J.D. Dale
LOCATION: Edmonton, Canada  ADDRESS: Dept. of Mech. Engineering
CLIMATE
Heating Degree Days: 5990  Univ. of Alberta
Cooling Degree Days: 30  Edmonton, Alberta
Global Solar Radiation: 1298 kWh/m²  Canada

BUILDING DESCRIPTION
Building Type: detached test buildings - 6 units
Construction Type: wood frame
Ground Coupling: basement
Number of Stories: 1
Auxiliary Fuel(s): electric
Auxiliary System(s): forced air - furnace
Number of Occupants: 0
Conditioned Floor Area: 98 m²
Aperture/Floor Area Ratio: 0.11
Global Heat Loss Coefficient: 120 W/degree K

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): direct gain
Passive Cooling System Type(s):
Thermal Storage Material:
Other Passive Component(s):

MONITORING
Level of Monitoring: A-
Monitoring Period: 1979 to present
Format of Data: computer tape
Quality of Data:

PERFORMANCE

REPORTS

NOTES
Facility consists of 6 detached test buildings. Description is for one unit only.
SITE CODE: DK-01

SITE NAME: Lyngby Solar House
LOCATION: Lyngby, Denmark

CONTACT: Lars Olsen
ADDRESS: Thermal Insulation
Technical University
2800 Lyngby
Denmark

CLIMATE
Heating Degree Days: 2829
Cooling Degree Days:
Global Solar Radiation: 1018 kWh/m²

TELEPHONE: 02 883511

BUILDING DESCRIPTION
Building Type: single detached
Construction Type: light weight concrete
Ground Coupling: insulated slab on grade
Number of Stories: 2
Auxiliary Fuel(s): electric
Auxiliary System(s):
Number of Occupants: 2
Conditioned Floor Area: 150 m²
Aperture/Floor Area Ratio: 0.11
Global Heat Loss Coefficient: 130 W/degree K

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): direct gain
Passive Cooling System Type(s):
Thermal Storage Material: tile on lightweight concrete floor
Other Passive Component(s):

MONITORING
Level of Monitoring: B
Monitoring Period: 11/82 to 9/83
Format of Data:
Quality of Data: 14 variables monitored continuously over 10 months
3 additional variables were monitored monthly

PERFORMANCE
Annual Heating Energy Balance - Passive Solar: 25%; Internal Gains: 20%;
Auxiliary: 55%. All monthly mean living space temperatures were between 17 degrees C and 27 degrees C. Only briefly during July and December do interior temperatures exceed the upper and lower user accepted limits.

REPORTS
Birkerod Solhus, Niels Mejlhede Jensen, Thermal Insulation Laboratory, Technical University of Denmark, Report NR 145, 1983. (Danish)

NOTES
SITE CODE: DK-02

SITE NAME: Lystoftevaenget
LOCATION: Lyngby, Denmark

CLIMATE
Heating Degree Days: 2829
Cooling Degree Days:
Global Solar Radiation: 1018 kWh/m²

BUILDING DESCRIPTION
Building Type: multi-family - 70 apartments
Construction Type: masonry
Ground Coupling: insulated slab on grade
Number of Stories: 2
Auxiliary Fuel(s): oil
Auxiliary System(s): oil burner
Number of Occupants: 1-4 (varies by unit)
Conditioned Floor Area: 4500 m²
Aperture/Floor Area Ratio: varies by apartment unit
Global Heat Loss Coefficient:

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): direct gain
Passive Cooling System Type(s):
Thermal Storage Material: brick (walls)
Other Passive Component(s):

MONITORING
Level of Monitoring: B-
Monitoring Period: 9/82 to 6/84
Format of Data:
Quality of Data: indoor dry bulb and auxiliary heating were monitored on a monthly basis over 21 months

PERFORMANCE

REPORTS
None as of June 1985.

NOTES
SITE NAME: SBI Low Energy House
LOCATION: Horsholm, Denmark

CLIMATE
Heating Degree Days: 2829
Cooling Degree Days:
Global Solar Radiation: 1018 kWh/m²

BUILDING DESCRIPTION
Building Type: row house
Construction Type: brick wall with cavity
Ground Coupling: insulated slab on grade
Number of Stories: 1.5
Auxiliary Fuel(s): electric
Auxiliary System(s): radiant ceiling
Number of Occupants: 2
Conditioned Floor Area: 100 m²
Aperture/Floor Area Ratio: 0.04
Global Heat Loss Coefficient: 100 W/degree K

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): direct gain
Passive Cooling System Type(s):
Thermal Storage Material: brick
Other Passive Component(s):

MONITORING
Level of Monitoring: B-
Monitoring Period: 1978 to 1983
Format of Data: hard copy
Quality of Data: 5 electricity consumption meters monitored auxiliary & water heating, lights & appliances over nearly 5 yrs

PERFORMANCE

REPORTS
SBI Low Energy House Model-79. Available from: SBI, P.O. Box 119, DK 2970, Horsholm, Denmark. (English)

NOTES
This is a low energy, well insulated row house with adjoining walls on north and west sides.
SITE CODE: NO-01

SITE NAME: Ivilde Solar House
LOCATION: Ivilde, Voss, Norway

CONTACT: M. Ringheim
ADDRESS: Kilde
Box 229
5701 Voss, Norway

CLIMATE
Heating Degree Days: 4200
Cooling Degree Days: 
Global Solar Radiation: 

BUILDING DESCRIPTION
Building Type: single detached
Construction Type: wood frame
Ground Coupling: basement
Number of Stories: 4
Auxiliary Fuel(s): 
Auxiliary System(s): 
Number of Occupants: 4
Conditioned Floor Area: 
Aperture/Floor Area Ratio: 
Global Heat Loss Coefficient: 

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): direct gain; sunspace
Passive Cooling System Type(s): earth contact
Thermal Storage Material: rock
Other Passive Component(s): 

MONITORING
Level of Monitoring: B
Monitoring Period: 1/81 to 1/83
Format of Data: hard copy
Quality of Data: 

PERFORMANCE
Heating Season Energy Balance - Passive Solar: 12%; Internal Gains: 51%
Auxiliary: 37%. The cost of providing the solar heat gain, including solar aperture,
storage and associated living space, is similar on a KWh basis, to the cost of
electric heating.

REPORTS
Enkel utnytting av solvarme i bustadhus." Available from: KILDE,
N-5701 Voss, Norway. (Norwegian)

NOTES
The monitoring was carried out to determine the solar heat gain improvements due
to minor modifications to a commonly used building design. The rock storage was
not insulated at time of monitoring.
SITE CODE: NO-02

SITE NAME: Trondheim Test Building
LOCATION: Trondheim, Norway

CLIMATE
Heating Degree Days: 4799
Cooling Degree Days: 
Global Solar Radiation: 912 kWh/m²

BUILDING DESCRIPTION
Building Type: 4 unit test building
Construction Type: wood frame
Ground Coupling: unheated crawl space
Number of Stories: 1
Auxiliary Fuel(s): electric
Auxiliary System(s): baseboards
Number of Occupants: 0
Conditioned Floor Area: 17 m²
Aperture/Floor Area Ratio: 0.14
Global Heat Loss Coefficient: 19 W/degree K

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): direct gain
Passive Cooling System Type(s): 
Thermal Storage Material: hollow concrete floor; ceiling panels (in Section C)
Other Passive Component(s): 

MONITORING
Level of Monitoring: B-
Monitoring Period: 1978 to 1980
Format of Data: hard copy
Quality of Data: approximately 9 variables measured for each test section

PERFORMANCE
Active thermal storage mass did not significantly reduce heating load, although it did increase comfort. Increased south glazing significantly increased the heat load.

REPORTS
Lavenergibygninger STF62 A30012." Available from: SINTEF 62, 7034 Trondheim - NTH, Norway. (Norwegian)

NOTES
north and a south room. The two middle sections are the subject of this report. One section (B) has been constructed with the economically optimum level of insulation, the other (C) the same as B with hollow concrete panels in floor and ceiling. Both are compared to the reference section A. Sections B and C each have south window area equal to 4 times the north window area. Window area in section is equally divided between north and south. Night insulation is not used. The global heat loss coefficient shown above is for Section B. In section C it is 10 W/degree K.

LOCATION: Tiller, Norway

CLIMATE
Heating Degree Days: 4799 at base temp. 18 C
Cooling Degree Days: 
Global Solar Radiation: 911 kWh/m²

BUILDING DESCRIPTION
Building Type: single detached
Construction Type: wood frame; masonry "double envelope"
Ground Coupling:
Number of Stories: 2
Auxiliary Fuel(s): electric
Auxiliary System(s): resistance heater
Number of Occupants: 4
Conditioned Floor Area: 120 m²
Aperture/Floor Area Ratio: 0.25
Global Heat Loss Coefficient:

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): sunspace; double shell
Passive Cooling System Type(s): ventilation
Thermal Storage Material: water drums
Other Passive Component(s):

MONITORING
Level of Monitoring: B
Monitoring Period: 10/82 to 5/84
Format of Data: hard copy; computer tape
Quality of Data: 18 variables monitored at 60 minute intervals for 19 months spanning 2 heating seasons

PERFORMANCE
On a typical summer day the sunspace temperature remains above 30 degrees C for 8 hours, and peaks above 45 degrees C. On a typical winter day the sunspace temperature appears to remain mid-way between indoor and outdoor temperatures.

REPORTS

NOTES
The sunspace covers the entire second floor on the south side. Warm air from the top of the sunspace is drawn down along the north roof and wall into the water barrel storage.

Level of Monitoring: B+
Monitoring Period: 3/82 to 3/83
Format of Data: hard copy
Quality of Data:

PERFORMANCE

REPORTS
Report will be available after September 1983 from the Department of Energy.

NOTES
Monitoring similar to standard SERI Class B procedures.
SITE NAME: Colton Conservation (Site WSE)  CONTACT: Solar Group
LOCATION: Colton, California  ADDRESS: Physics Department
              California State University
              6000 J Street
              Sacramento, CA 95819

CLIMATE
Heating Degree Days: 1066  TELEPHONE: (916) 454-6518
Cooling Degree Days: 736
Global Solar Radiation: 1862 kWh/m²

BUILDING DESCRIPTION
Building Type: single detached
Construction Type: masonry
Ground Coupling: slab on grade
Number of Stories: 1
Auxiliary Fuel(s): propane
Auxiliary System(s): forced air
Number of Occupants: 2
Conditioned Floor Area: 154 m²
Aperture/Floor Area Ratio: 0.03
Global Heat Loss Coefficient: 307 W/degree K

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): direct gain
Passive Cooling System Type(s): ventilation
Thermal Storage Material: lightweight building materials
Other Passive Component(s): none

MONITORING
Level of Monitoring: B+
Monitoring Period: 7/81 to 9/82
Format of Data: 9-track magnetic tape, 1600 or 6250 BPI
Quality of Data: good continuous year of data

PERFORMANCE
Heating Season Energy Balance - Passive Solar: 35%; Internal Gains: 46%;
Auxiliary: 18%. Despite the much smaller aperture and thermal mass of this house,
it achieved energy savings almost equal to site US/CA-08.

REPORTS

A Guide to using the Class B Passive Solar Performance Data, William A. Kolar,
SERI/SP-254-2248, Solar Energy Research Institute, 1984

Performance of Passive Solar and Energy Conserving Houses in California,

NOTES
This is a reference conservation design similar to site US/CA-08.
SITE CODE: US/CA-15

SITE NAME: Sacramento Solar Condo (Site WSK) CONTACT: Solar Group
LOCATION: Sacramento, California ADDRESS: Physics Department
CLIMATE Heating Degree Days: 1601 California State University
Cooling Degree Days: 483 6000 J Street
Global Solar Radiation: 1832 kWh/m² Sacramento, CA 95819
TELEPHONE: (916) 454-6518

BUILDING DESCRIPTION
Building Type: central unit of 6 unit building
Construction Type: wood frame
Ground Coupling: slab on grade
Number of Stories: 2
Auxiliary Fuel(s): electric
Auxiliary System(s): heat pump (forced air)
Number of Occupants: 1
Conditioned Floor Area: 132 m²
Aperture/Floor Area Ratio: 0.15
Global Heat Loss Coefficient: 179 W/degree K

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): direct gain
Passive Cooling System Type(s): ventilation; shading
Thermal Storage Material: concrete slab
Other Passive Component(s): none

MONITORING
Level of Monitoring: B+
Monitoring Period: 12/81 to 3/83
Format of Data: 9-track magnetic tape, 1600 or 6250 BPI
Quality of Data: ten months of almost continuous data

PERFORMANCE
Heating Season Energy Balance - Passive Solar: 25%; Internal Gains: 36%;
Auxiliary: 39%. The relatively low heat loss coefficient kept the purchased energy
low despite the low solar contribution. Interior temperatures were very stable.

REPORTS

A Guide to Using the Class B Passive Solar Performance Data, William A. Kolar,
SERI/SP-254-2248, Solar Energy Research Institute, 1984

Performance of Passive Solar and Energy Conserving Houses in California,
Golden, CO: Solar Energy Research Institute

SITE CODE: US/CA-16

SITE NAME: Rio Linda Conservation (Site WSL) CONTACT: Solar Group
LOCATION: Rio Linda, California ADDRESS: Physics Department
CLIMATE
Heating Degree Days: 1601 California State University
Cooling Degree Days: 483 6000 J Street
Global Solar Radiation: 1832 kWh/m² Sacramento, CA 95819

TELEPHONE: (916) 454-6518

BUILDING DESCRIPTION
Building Type: Single dwelling
Construction Type: wood frame
Ground Coupling: slab on grade
Number of Stories: 1
Auxiliary Fuel(s): natural gas
Auxiliary System(s): forced air
Number of Occupants: 3
Conditioned Floor Area: 111 m²
Aperture/Floor Area Ratio: 0.03
Global Heat Loss Coefficient: 176 W/degree K

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): direct gain
Passive Cooling System Type(s): shading
Thermal Storage Material: concrete slab
Other Passive Component(s): none

MONITORING
Level of Monitoring: B+
Monitoring Period: 2/82 to 9/82
Format of Data: 9-track magnetic tape, 1600 or 6250 BPI
Quality of Data: nine months of almost continuous data

PERFORMANCE
Heating Season Energy Balance - Passive Solar: 6%; Internal Gains: 50%;
Auxiliary: 44%. Largely due to a smaller heat loss rate, this house used less
auxiliary heat than the otherwise similar solar design, site US/CA-14.

REPORTS

CLIMATE
Heating Degree Days: 3342
Cooling Degree Days: 347
Global Solar Radiation: 1805 kWh/m²

BUILDING DESCRIPTION
Building Type: single detached
Construction Type: wood frame
Ground Coupling: basement
Number of Stories: 2
Auxiliary Fuel(s): natural gas
Auxiliary System(s): forced air
Number of Occupants: 2
Conditioned Floor Area: 301 m²
Aperture/Floor Area Ratio: 0.14
Global Heat Loss Coefficient: 423 W/degree K

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): direct gain; sunspace
Passive Cooling System Type(s): ventilation; shading
Thermal Storage Material: concrete basement; brick floor & walls
Other Passive Component(s): none

MONITORING
Level of Monitoring: B+
Monitoring Period: 4/81 to 9/82
Format of Data: 9-track magnetic tape, 1600 or 6250 BPI
Quality of Data: January and June data missing from 14 months of data collection

PERFORMANCE
Heating Season Energy Balance - Passive Solar: 50%; Internal Gains: 15%;
Auxiliary: 35%. The building has a high heat loss coefficient due to high infiltration.

REPORTS

A Guide to Using the Class B Passive Solar Performance Data, William A. Kolar,
SERI/SP-254-2248, Solar Energy Research Institute, 1984

NOTES
Most of main floor is a large room receiving gain through the sunspace, from skylights and other south windows. House mainly occupied on weekends. Sunspace doors to house interior only opened on sunny days during weekends, thus warming interior. Closed sunspace overheated on sunny weekdays, often exceeding 32 degrees C.
SITE CODE: US/CO-06

SITE NAME: Westminster House (Site DMF) CONTACT: Building Systems Branch

CLIMATE
Heating Degree Days: 3342 1617 Cole Blvd.
Cooling Degree Days: 347 Golden, CO 80401
Global Solar Radiation: 1805 kWh/m² TELEPHONE: (303)231-7186

BUILDING DESCRIPTION
Building Type: single detached
Construction Type: wood frame
Ground Coupling: basement
Number of Stories: 2
Auxiliary Fuel(s): natural gas
Auxiliary System(s): forced air
Number of Occupants: 2
Conditioned Floor Area: 174 m²
Aperture/Floor Area Ratio: 0.15
Global Heat Loss Coefficient: 284 W/degree K

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): direct gain
Passive Cooling System Type(s): ventilation; shading
Thermal Storage Material: brick veneer walls; rock bin
Other Passive Component(s): insulated shades on south

MONITORING
Level of Monitoring: B+
Monitoring Period: 4/81 to 6/83
Format of Data: 9-track magnetic tape, 1600 or 6250 BPI
Quality of Data: 1 month of data missing from 23 months
of continuous monitoring

PERFORMANCE
Despite a solar aperture of 15% of floor area, the solar performance was disappo
pointing with less than 40% of mid-winter heating load met by the passive system. Rock
bin storage system did not function adequately, causing heavily glazed living room to
overheat often above 29 degrees C. The house experienced large temperature swings.

REPORTS

A Guide to Using the Class B Passive Solar Performance Data, William A. Kolar,
SERI/SP-254-2248, Solar Energy Research Institute, 1984

NOTES

BUILDING DESCRIPTION
Building Type: single detached
Construction Type: wood frame
Ground Coupling: slab on grade
Number of Stories: 2
Auxiliary Fuel(s): electric
Auxiliary System(s): forced air (switched to natural gas)
Number of Occupants: varies
Conditioned Floor Area: 200 m²
Aperture/Floor Area Ratio: 0.14
Global Heat Loss Coefficient: 327 W/degree K

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): direct gain; sunspace
Passive Cooling System Type(s): ventilation; shading
Thermal Storage Material: tile floor in solarium
Other Passive Component(s): insulating night curtain on solarium glazing

MONITORING
Level of Monitoring: B+
Monitoring Period: 11/81 to 6/83
Format of Data: 9-track magnetic tape, 1600 or 6250 BPI
Quality of Data: monitoring period: 11/81 to 6/83; information
completeness of data is not available

PERFORMANCE
Auxiliary: 26%.

REPORTS

A Guide to Using the Class B Passive Solar Performance Data, William A. Kolar, 
SERI/SP-254-2248, Solar Energy Research Institute, 1984

NOTES
This is a manufactured panelized house with a 2 story solarium. The solarium is 
open to the living area and can be vented to the attic. Occupancy is atypical. It 
is a sales model, thus unoccupied during the night. The thermostat setting was 
about 13 degrees C.
SITE CODE: US/CT-01

SITE NAME: Tolland House (Site NEC)  CONTACT: Building Systems Branch

CLIMATE
Heating Degree Days: 3528
Cooling Degree Days:
Global Solar Radiation: 1219 kWh/m² TELEPHONE: (303)231-7186

BUILDING DESCRIPTION
Building Type: single detached
Construction Type: wood frame
Ground Coupling: slab on grade
Number of Stories: 1
Auxiliary Fuel(s): electric
Auxiliary System(s): baseboard
Number of Occupants: 4
Conditioned Floor Area: 162 m²
Aperture/Floor Area Ratio: 0.13
Global Heat Loss Coefficient: 251 W/degree K

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): direct gain; sunspace
Passive Cooling System Type(s): shading
Thermal Storage Material: brick faced concrete wall; concrete slab floor
Other Passive Component(s): insulating drapes & sliding panels for windows

MONITORING
Level of Monitoring: B+
Monitoring Period: 9/81 to 4/83
Format of Data: 9-track magnetic tapes; hard copy
Quality of Data: 1 month missing data (available soon)
in 21 continuous months of monitoring

PERFORMANCE
Occupants kept north bedroom doors closed, thus solar gain had little effect on these
rooms where the day time temperature would drop below 15 degrees C even on sunny days.

REPORTS

A Guide to Using the Class B Passive Solar Performance Data, William A. Kolar,
SERI/SP-254-2248, Solar Energy Research Institute, 1984

NOTES
Two sets of sliding glass doors provide some control over heat flows between the
sunspace and other zones.

PERFORMANCE

REPORTS
Report available from MA Executive Office of Energy Resources, 100 Cambridge St.,
Room 1500, Boston, MA 02202.

NOTES
SITE NAME: Hamilton House (Site NEA)  CONTACT: Building Systems Branch
               1617 Cole Blvd.
               Golden, CO 80401

CLIMATE
Heating Degree Days: 3123
Cooling Degree Days:
Global Solar Radiation: 1272 kWh/m²  TELEPHONE: (303)231-7186

BUILDING DESCRIPTION
Building Type: single detached
Construction Type: masonry
Ground Coupling: slab on grade; earth sheltered
Number of Stories: 2
Auxiliary Fuel(s): electric
Auxiliary System(s): heat pump
Number of Occupants: 3
Conditioned Floor Area: 195 m²
Aperture/Floor Area Ratio: 0.19
Global Heat Loss Coefficient: 263 W/degree K

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): direct gain
Passive Cooling System Type(s): earth contact; shading
Thermal Storage Material: concrete block; concrete slab
Other Passive Component(s): movable insulation

MONITORING
Level of Monitoring: B+
Monitoring Period: 10/81 to 5/83
Format of Data: 9-track magnetic tape, 1600 or 6250 BPI
Quality of Data: majority of data available, 4 months of 81-82 & 5 months of 82-83 heating seasons

PERFORMANCE
Heating Season Energy Balance - Passive Solar: 26%; Internal Gains: 18%;
Auxiliary: 56%. The house has a relatively low infiltration rate, due to the extensive use of earth berming. However, heat loss coefficient is relatively high because of the large glazing area. The solar contribution was 34% of the heating load in January but decreased in spring, probably because of large overhang above the major direct gain component. The building's ability to retain solar heat was disappointing, as the auxiliary heaters activated soon after sundown on sunny winter days. This should improve with the use of night insulation.

REPORTS

Passive Solar Performance: Summary of 1982-83 Class B Results, SERI,

A Guide to Using the Class B Passive Solar Performance Data, William A. Kolar,

Global Solar Radiation: 1213 kWh/m²

BUILDING DESCRIPTION
Building Type: single detached
Construction Type: wood frame
Ground Coupling: crawlspace; partial floor slab over deck
Number of Stories: 1
Auxiliary Fuel(s): electric
Auxiliary System(s): wall heaters
Number of Occupants: 2
Conditioned Floor Area: 118 m²
Aperture/Floor Area Ratio: 0.07
Global Heat Loss Coefficient: 138 W/degree K

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): direct gain
Passive Cooling System Type(s): ventilation
Thermal Storage Material: concrete slab
Other Passive Component(s): 

MONITORING
Level of Monitoring: B+
Monitoring Period: 10/82 to 9/83
Format of Data: 9-track magnetic tape, 1600 or 6250 BPI
Quality of Data: majority of data available for one year

Heating Degree Days: 4660
Cooling Degree Days:  
Global Solar Radiation: 1304 kWh/m²  TELEPHONE: (303)231-7186

BUILDING DESCRIPTION
Building Type: single detached
Construction Type: wood frame
Ground Coupling: basement
Number of Stories: 1
Auxiliary Fuel(s): propane
Auxiliary System(s): forced air
Number of Occupants: 2
Conditioned Floor Area: 168 m²
Aperture/Floor Area Ratio: 0.19
Global Heat Loss Coefficient: 163 W/degree K

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): direct gain; sunspace
Passive Cooling System Type(s): ventilation
Thermal Storage Material: brick walls; concrete floor
Other Passive Component(s): movable insulation

MONITORING
Level of Monitoring: B+
Monitoring Period: 5/81 to 7/82
Format of Data: 9-track magnetic tape, 1600 or 6250 BPI
Quality of Data: majority of 5 months of continuous data available

PERFORMANCE
Heating Season Energy Balance - Passive Solar: 26%; Internal Gains: 17%;
Auxiliary: 56%. Due to the efficiency of the building envelope, the auxiliary heating needs were low for such a cold climate. The solar component contributed 26% of the winter heating load. Although the solarium temperature fluctuated a great deal, the temperature in the rest of the house was more stable and comfortable.

REPORTS

Heating Degree Days: 4660
Cooling Degree Days:
Global Solar Radiation: 1304 kWh/m²  TELEPHONE: (303)231-7062

BUILDING DESCRIPTION
Building Type: duplex, mobile home
Construction Type: wood frame
Ground Coupling: crawl space
Number of Stories: 1
Auxiliary Fuel(s): propane
Auxiliary System(s): forced air
Number of Occupants: varies
Conditioned Floor Area: 94 m²
Aperture/Floor Area Ratio: 0.08
Global Heat Loss Coefficient: 127 W/degree K

PASSIVE SOLAR SYSTEMS
Passive Heating System Type(s): direct gain
Passive Cooling System Type(s): ventilation
Thermal Storage Material: lightweight building materials
Other Passive Component(s): movable insulation

MONITORING
Level of Monitoring: B+
Monitoring Period: 12/81 to 1/83
Format of Data: 9-track magnetic tape, 1600 or 6250 BPI
Quality of Data: limited data in archive

PERFORMANCE
Heating Season Energy Balance - Passive Solar: 34%; Internal Gains: 4%.
Auxiliary: 62%. Much of the relatively small heat loss is due to infiltration.
With the building unoccupied the internal temperature was allowed to float, and
without significant mass it often exceeded 27 degrees C. Such overheating would
normally result in venting, thus reducing the net solar gains.

REPORTS

A Guide to Using the Class B Passive Solar Performance Data, William A. Kolar,
SERI/SP-254-2248, Solar Energy Research Institute, 1984

NOTES
5. PERFORMANCE DATA FOR SYSTEM EVALUATION FORMS

This chapter contains more detailed information on some of the monitored buildings described in Chapter 4. Drawings and photographs are presented to more fully illustrate the architectural character of the passive solar homes. Also, performance data is presented for a typical summer and winter day and for annual energy performance. Findings from the monitoring program are also summarized. Together, this information provides greater insight into the design, construction, operation and performance of the monitored passive solar projects than provided in Chapter 4. This information should assist the reader in selecting candidate projects from which to obtain performance data.
Performance data for systems evaluation

PROJECT TITLE
Direct gain house with integrated sunspace.
BE-01

BUILDING AND SYSTEM DESCRIPTION
(plans, sections, system schematics showing energy flows, key components and modes of operation)

1st LEVEL

2nd LEVEL

SYSTEM SCHEMATIC

Fuel burner
CONCLUSIONS/FINDINGS  (thermal comfort, user acceptance, costs, etc...) 

The sunspace is the most important area of this house and has essentially an 
horticultural reason. 

It's also important to note that the auxiliary heating provides for a very big 
part form the wood oven which is placed in the living.

Source of Information: 143
Passive and Hybrid Solar Low Energy Buildings

Performance data for systems evaluation

**PROJECT TITLE**
Direct gain house with added sunspace and solar collector.
BE-02

**BUILDING AND SYSTEM DESCRIPTION**
(plans, sections, system schematics showing energy flows, key components and modes of operation)

**SYSTEM SCHEMATIC**

**Collectors:**
1. sunspace (33m²) with mass wall storage.
2. solar collector with water storage (30m³)

**Distribution:**
1. radiation and convection from wall storage
2. radiators using energy from the water storage

**Auxiliary:** fuel burner

**DHW:** from the same solar collector

**Controls:**
- always priority to DHW boiler
- differential thermostat to control storage or burner
CONCLUSIONS/FINDINGS (thermal comfort, user acceptance, costs, etc...)
The direct solar gains were essentially researched during the pre-design of the house (choice of materials, orientation of glazing, attached sunspace). The monitoring has shown a very low energy load so that on an economical point of view, the active system (solar collector) can difficultly be justified.

Source of Information: 145
Performance data for systems evaluation

PROJECT TITLE
Direct gain house with integrated sunspace and trombe wall.
BE-03

BUILDING AND SYSTEM DESCRIPTION
( plans, sections, system schematics showing energy flows, key components and modes of operation )

GROUND FLOOR

AXONOMETRY

SYSTEM SCHEMATIC

146
CONCLUSIONS/FINDINGS (thermal comfort, user acceptance, costs, etc...) The direct solar gains were essentially researched during the predesign of the house.

The integrated sunspace has two functions:
- solar captor and horticultural

That's the reason why it's necessary to maintain there 10°C minimum.

The hot water production needs to use continually the gaz burner as shown with system schematic. That system has to be modify.

Finally, it's a pity that the house is not better insulated.

BUILDING AND SYSTEM DESCRIPTION
( plans, sections, system schematics showing energy flows, key components and modes of operation )

ORIGINAL DESIGN:

MODIFIED BUILDING:

What solar energy gains can be obtained by relatively small modifications to a commonly used building design? This question was the starting point for the project.
CONCLUSIONS/FINDINGS (thermal comfort, user acceptance, costs, etc...)  
The building modifications have resulted in significant solar energy gains, but have also resulted in additional living space, a veranda and additional cellar space, for a total cost of approx. 45000 kr (1980). For a similar building on more suitable foundations it should be possible to obtain similar results at 60% - 70% of the costs. By estimating a user value for the additional living space, the kwh price for solar energy will be similar to the electricity price.

By use of solar energy and wood plus improved insulation it is not difficult to reduce the demand for electricity/oil heating in a dwelling by 50% relative to the typical 1950-80 dwelling. The rock heat storage is not yet insulated, and has mainly acted as a cooling source on very hot days.

Heat provided by passive solar
Heat provided by internal generation
Heat provided by auxiliary system

Annual Summary

Section B: 0.5 MWh incl. internal gain (light bulbs).

Heating Load Provided by Passive Solar

Heating Load Provided by Internal Generation

Heating Load Provided by Auxiliary Heating 100 %

CONCLUSIONS/FINDINGS (thermal comfort, user acceptance, costs, etc...)

- South room in reference section (A) has lower demand than north room (same window area)
- South room in section B and C consumed more energy than north room (window area south 4* window area north). There is no night insulation. This means net heat loss even through "good" windows (K=1.0 W/m²K)
- Active mass does not reduce the heating demand (significantly), though the comfort level in C is much better than in B
- Extra insulations works! B 46 % of A.
- Due to technical problems in construction, the heat loss in sect. C is too large. Problems: Cold bridges, air leakages both to rooms and inside insulations.

**DOUBLE SHELL HOUSE AT ÅS**
**DANSKERUD**
**1430 ÅS, NORWAY**

**BUILDING AND SYSTEM DESCRIPTION**

**COLLECTORS:**
- Sunspace 14 m²
- Air collector 45 m²

**STORAGE:**
- Rock bed 13 m³

**DISTRIBUTION:**
Closed loop circulation - from collector via storage to air space in walls and attic.

**VENTILATION:**
Fresh air supplied via solar heat loop.

**PREHEATING OF HOT WATER:**
150 m polyethylene pipe in rock storage.
CONCLUSIONS/FINDINGS (thermal comfort, user acceptance, costs, etc...)

- The building has a considerably lower heating load than other buildings with comparable insulation standards. This is in part due to the double skin construction which eliminates heat loss to the ground, and which provides preheating of the ventilation air.

- The building works most fully during the middle of the winter, whereas conventional solar systems produce the least amount of additional energy at these latitudes.

- The preheating of hot water does not function satisfactorily, as the heat flow from the rock bed to the ground during the summer is greater than expected.

- The costs involved are quite high, but are justified by the fact that the building is a prototype.

PROJECT TITLE
STR, LÄGENERGIPROJEKT FÖR SÍMAHUS.

BUILDING AND SYSTEM DESCRIPTION
(plans, sections, system schematics showing energy flows, key components and modes of operation)
CONCLUSIONS/FINDINGS (thermal comfort, user acceptance, costs, etc...) 

Overheating hasn't been a problem. In one year the indoor temperature has been higher than +26 C only during a couple of days. This happened when the house was unoccupied. Once the house is occupied, the occupants can be expected to use curtains and open windows in order to lower the temperature. The mechanical ventilation rate can be controlled by the occupants. During nights the system was usually turned off as the supply devices were too noisy.

Performance data for systems evaluation

PROJECT TITLE
SW-02

BUILDING AND SYSTEM DESCRIPTION
( plans, sections, system schematics showing energy flows, key components and modes of operation )

Figure 1. The Ulmüs house
Figure 2. Solar heating system
CONCLUSIONS/FINDINGS (thermal comfort, user acceptance, costs, etc...)
The sunspace is an area which can be used as a living space during most of the year. An area which doesn't require any space-heating, instead it contributes to the space-heating of the building itself. This contribution was 4600 kWh.
The indoor temperature (excl. sunspace) rarely went above +30 °C thanks to the sunspace working as a thermal buffer.
Thermal shutters should be installed in the sunspace to decrease night time heat losses. During the summer when it is sunny and warm the sunspace should be opened i.e. the whole south window of the sunspace should be pushed aside and the windows up by the roof opened.

Performance data for systems evaluation

PROJECT TITLE
PASSIVE SOLAR ONE FAMILY HOUSE
WITH GREENHOUSE AND SOLID BRICKWALL
IN FÄRGELENGA, SWEDEN

BUILDING AND SYSTEM DESCRIPTION

first floor

Ground floor Shedule 1:200
CONCLUSIONS/FINDINGS (thermal comfort, user acceptance, costs, etc...) 

Thanks to the solid brickwall which makes the temperature-variation even, the thermal comfort in the house is high. During the summer hardly no sun radiation gets into the house, because the windows are effectively shadowed, which makes the house more comfortable than comparable standard houses. No auxiliary cooling is needed. The users accept a temperature-variation of 20-24°C during the winter, which makes the energy needed for heating low, 2500 - 5000 kWh/year.

The house is financed with ordinary governmental housing loans and is not especially expensive, compared with an ordinary house.

PROJECT TITLE
VALENCIA - LOW ENERGY
TERACED HOUSES
SW-04

BUILDING AND SYSTEM DESCRIPTION
( plans, sections, system schematics showing energy flows, key components and modes of operation )
CONCLUSIONS/FINDINGS (thermal comfort, user acceptance, costs, etc...)

The figures are measured data from our special monitored measuring-house witch is a gable house. The mean indoor temperature during this year was 22.5 °C. The insulation and tightness of the houses and the heat recovery on the ventilation have reached the expectations and the heat power required in the houses is not higher than calculated. The water-carried radiator system however has uncontrolled losses of heat through insufficiently insulated hot water pipes. Even when all the radiators are turned off, the hot water pipes are emitting large amounts of heat. This problem causes a limited heat control. Free heat like solar radiation, domestic electricity and heat from people does not lead to a reduction of the energy consumption. The only result is a rise of the indoor temperature.

BUILDING AND SYSTEM DESCRIPTION
(plans, sections, system schematics showing energy flows, key components and modes of operation)

Figure 0.5: Section through one of the houses

Figure 2.12: Schematic section through the group heating plant building.

Figure 0.3: A simplified diagram of the heating system

Figure 4.1: Simplified energy flow diagram.
CONCLUSIONS/FINDINGS (thermal comfort, user acceptance, costs, etc...)

Future houses should incorporate measures for reducing transmission losses through the building envelope and the ventilation losses due to air infiltration. With the current low price of electricity the houses should ideally have been heated with electric base board heaters. The solar group heating plant in this project is not profitable today, especially on such a small scale being connected only to six houses.

BUILDING AND SYSTEM DESCRIPTION

GROUND FLOOR

FIRST FLOOR

SECOND FLOOR
CONCLUSIONS/FINDINGS (thermal comfort, user acceptance, costs, etc...) THEY HAVE SUCCESSED IN HOLDING THE TEMPERATURE IN THE SUNSPACE DOWN TO 2-3°C ABOVE THE OUTDOOR TEMPERATURE THIS SUMMER. THIS HAS BEEN POSSIBLE BY AN EFFICIENT USE OF THE CURTAINS AND SHUTTERS.

IT WILL BE EVEN MORE INTERESTING TO FOLLOW THE COMING WINTER WHEN WE, AMONG OTHER THINGS, WILL BE ABLE TO SEE WHAT HAPPENS WITH THE TEMPERATURE IN THE SUNSPACE. IF THE TEMPERATURE GOES DOWN BELOW ABOUT 5°C THEN THE PLANTS MAY HAVE DIFFICULTIES OF SURVIVING.
The entire south wall of this small one-floor house in central Arizona is a double-glazed greenhouse. Glass panels in a massive storage wall allow direct gain through the greenhouse to the house interior. Thermal storage is provided by the mass wall, the concrete, brick and tile floor and a forced-air-fed rock storage bin under the north half of the house. Summer cooling is by controlled venting from the top of the greenhouse to prevent daytime overheating and provide night cooling of the storage masses. Exterior roll-down shades provide additional protection against overheating.
In 1980-81, solar energy supplied 53.02 GJ of the 69.24 GJ building heating load for a solar fraction of 77%. The solar system performed smoothly and efficiently throughout the heating season. Except for 10.54 MJ of electric heat, all of the auxiliary heating energy used was supplied by the wood stove in the living room.

It was found that a pulse of heat took approximately 4.5 hours to travel through the Trombe wall. It was suggested that this relatively long time may be due in part to the fact that the hollow blocks in the wall are filled with loose sand which does not conduct heat as well as the solid concrete.
This single detached residence is located in Davis, California. The system uses 25.4 square meters of direct-gain collector, part of which is in a 7.5 square meter clerestory. Solar energy is stored in a series of steel tubes filled with 13,626 liters of water. Additional storage is supplied by the floor slab. Night-time losses are reduced by the use of insulating curtains on the windows and shutters on the clerestory. Auxiliary energy is supplied by a wood stove and a gas-fired wall furnace.
The overall performance of the system was very good with an annual solar fraction of 80%. If the internal gains had been lower for January and February, the system could have used more solar energy and the annual solar fraction would have been higher.

The system was designed with a good collector to storage ratio which prevented large temperature swings inside the building.

The heating season began with an average storage temperature of 24°C. The storage temperature decreased during the winter, and by February the average storage temperature was 20°C. This drop in temperature accounts for the fact that more energy was delivered from storage than was delivered to storage. The additional energy delivered from storage was energy collected during the summer months and released during the heating season.

The overall system performance suffered somewhat due to the manual operation of the movable insulation. The net savings from the use of the movable insulation were 3.56 GJ, but because the shutters and curtains were only open to collect 56% of the available solar energy, 16.27 GJ of solar energy were lost or not collected (based on average collection efficiency of 69%).

(by Vitro Labs for NSPUP)
This small single-story slab-on-grade house comprises the western half of a duplex. It receives direct gain through south windows and a 45° tilted clerestory. The clerestory glazing charges 1100 gallons (4169 L) of water contained in four steel cylinders. Warm air from the clerestory is ducted to the north bedrooms. The clerestory also serves as a solar chimney, which can be opened to vent warm air during the summer.
CONCLUSIONS/FINDINGS

The solar components met more than 60% of the heating load with little auxiliary heating needed. The interior temperature was allowed to fluctuate a great deal, often falling below 60°F (16°C) during cloudy weather.

This two-story slab-on-grade house in north-central California has a large attached greenhouse. The greenhouse has both vertical glazing and skylights. There are barrels filled with 385 gallons (1459 L) of water along the north wall of the greenhouse. One-third of this wall is glazed to allow direct solar gain to the living space. Clerestory windows provide direct gain to the second floor and open to allow venting of warm air.
CONCLUSIONS/FINDINGS

Despite the large glazing areas, the heat loss coefficient was relatively small due to the low infiltration rate of 0.16 air change per hour. The solar components met about half the winter heating load, with decreased performance only during a very cloudy December. The greenhouse was generally not open to the interior living space, resulting in large greenhouse temperature swings. The interior temperature was stable, however, with no tendency to overheat. Wood burning is included in the monthly auxiliary heating figures. It does not appear as auxiliary heating on the hourly data plot, but wood use is obvious from the sudden indoor temperature increases in the evenings.

(by J. Swisher & T. Corning)
This large two-story frame house is located near the northern California coast. South windows, skylights, and clerestory windows provide 367 ft² (34.1 m²) of direct gain solar aperture. There are also 114 ft² (10.6 m²) of east-facing windows. A rock bed located beneath the west rooms can be charged by warm air that is drawn from near the clerestory by a thermostatically controlled fan. This system was not in operation during the monitoring period.
CONCLUSIONS/FINDINGS

The solar heating contribution was about 60% of the heating load throughout the winter months. In the cool coastal climate, the solar components continue to provide useful heat year-round. There was little overheating. However, the interior temperature swings were large on sunny days, and the temperature dropped below 60°F (16°C) during cloudy winter weather. Wood burning is included in the monthly auxiliary heating figures. It does not appear as auxiliary heating on the hourly data plot, but wood use is obvious from the sudden indoor temperature increases in the evenings.

This small house is located in the Sierra Nevada mountains of eastern California. Large direct gain windows charge a two-story solarium which has an exposed slab floor. A 20 cm-thick adobe wall extends from ground level to 1 meter above the second floor level.
The solar component met about half the winter heating load. Most of the remaining energy requirement was met by internal heating from a hot tub located in the solarium. The average indoor temperature is low because the occupant kept the bedrooms at 50°F (10°C) or below at night, often opening a bedroom window even in mid-winter. Wood burning is included in the monthly auxiliary heating figures. It does not appear as auxiliary heating on the hourly data plot, but wood use is obvious from the sudden indoor temperature increases in the evenings.

Performance data for systems evaluation

PROJECT TITLE
US/CA-15
Sacramento, California

BUILDING AND SYSTEM DESCRIPTION

This two-story condominium in downtown Sacramento has common east and west walls. It receives direct solar gain from south windows and a clerestory. The first-floor slab is partly exposed for thermal mass.
The solar contribution was only 25% of the total heating load due to the shading problem and the cloudy Sacramento winter weather. The relatively low heat loss coefficient helped keep the purchased energy use low. The interior temperature was very stable, staying between 65°F and 70°F (18°C-21°C) about 90% of the time.

CONCLUSIONS/FINDINGS

This suburban Denver single-story home uses earth-sheltering and direct gain to minimize auxiliary heating needs. The roof and north, east and west walls are covered with earth. Thermal storage is provided by the 10 cm thick floor slab, 20 cm thick externally insulated concrete walls and fifty-two 200-liter water-filled drums located immediately behind the south glazing. Beadwall movable insulation reduces night-time heat losses from the 36 square meters of south glazing. Heat distribution is by convection and radiation. A plenum between the roof and the ceilings of the rooms carries warm air rising off of the water drums to the north side of the house.
Solar energy supplied 30.45 GJ of the 44.65 GJ building heating load for a solar fraction of 68%. These savings were realized at an expense of 243 kwh of electricity to operate the Beadwall®. Auxiliary energy was supplied by the fireplace. Temperatures in the building averaged 23°C during this time. The maximum temperature observed during the heating season was 30°C and the minimum was 15°C. Interestingly, the overheating occurred in mid-November as the result of the use of the fireplace.

Q Summer cool-air inlet
R Auxiliary heat: Electric baseboards, fireplace
S Thermal buffers
T Garage, bathrooms
U Air-lock entryway
V Earth berm
CONCLUSIONS/FINDINGS

This is a two-story building with a relatively large solar aperture area (15% of the floor area) divided between an attached sunspace and a site-built, south-wall air heater. The air heater charges a 300-ft³ (8.5-m³) rock bin located under the northern half of the house. The sunspace has both vertical and sloped glazing and a slate floor. It is separated from the living area by a concrete wall and four 450-gal (1700-L) water-filled tubes. The sunspace also contains a hot tub, providing additional mass and, because it's used frequently, a significant internal heating source.

The solar components were effective, contributing about 60% of the heating load during the winter. This high passive heating ratio was partly because of relatively low indoor temperatures, averaging 55°F (18°C). Individually controlled electric room heaters allowed the occupants to heat a small area of the building, resulting in low overall building temperatures and efficient use of solar and electric energy.

E Slab floor with tile surface
F Concrete foundation walls

Heat distribution:
G Paddle fans
H Louvered power-exhaust vent
J Furnace return-air duct from solarium

Auxiliary heat:
K Woodstoves (2)
L Gas forced-air furnace
M Partial earth berm
N Air-lock entryway
CONCLUSIONS/FINDINGS

This is a large, two-story house with the north side bermed so that the lower level is below grade. A large direct-gain component charges a two-story solarium, which is open to most interior rooms. The solarium has a tile floor and is backed by an 8-in. (20-cm)-thick concrete wall with brick veneer. Two small ceiling fans in the solarium also help distribute warm air. The south windows are fitted with manually operated insulating shutters; however, the shutters are usually left open.

The building's heat loss coefficient, though relatively high, is low for such a large building. The solar component provided nearly 60% of the winter heating load before the building was occupied, and about 50% thereafter (when the indoor temperature was kept 4°F (2°C) higher). The excellent interior air circulation heated the building very evenly on sunny days and prevented overheating in the solarium.

H. Thermostatically controlled fan
J. Powered destratification units (circulate heat from loft, ceilings)
Auxiliary heat:
K. Gas forced-air furnace
M. Brick/altar fireplace
Thermal buffers:
N. North-zoned garage, bedrooms
P. Air-lock entryway
CONCLUSIONS/FINDINGS

This house is a large two-story design with an attached sunspace and a basement. Most of the main level is an open great room that receives direct gain through the sunspace, from skylights, and from additional south windows. The great room is also open to a loft above. The upper level and the basement also have south windows.

The sunspace has a tile floor and both vertical and sloped glazing. The design includes a thermostatically controlled fan to dump warm sunspace air into the basement. Apparently this fan was not used, however, since the sunspace performance depended on the presence of the homeowners. During the week, the house was usually empty, with the sunspace doors left closed (because the sunspace was quite cold in the morning). On sunny winter days, the sunspace temperature exceeded 90°F (32°C); but with the doors closed, the interior remained cool and the backup furnace was needed in the early evening. On weekends, the homeowners were usually home and opened the sunspace doors on sunny days. This resulted in a cooler sunspace, a warmer interior, and less furnace use in the evening.

The building’s heat loss coefficient was extremely large, due to infiltration. It was not possible to pressurize the building adequately for an infiltration test. The builders were informed of this and have had better results with their more recent buildings based on this design. The solar component performed well, meeting about half of the large heating load. Tighter construction and better control of heat distribution could increase this percentage considerably.

Thermal buffer:
L. Air-lock entryway

Upper Floor Plan

Lower Floor Plan

South elevation
CONCLUSIONS/FINDINGS

This is a townhouse unit with common east and west walls. A two-story attached sunspace, with both vertical and sloped glazing, forms the south end of the unit. The sunspace is separated from the main living space by a brick wall, which has sliding glass doors to both levels, allowing some direct solar gain. A thermostatically controlled fan draws warm air from the sunspace to charge a rock bin under the north rooms.

With little exposed surface area, the building's heat loss coefficient is quite low. Such that internal heat generation supplied more than 20% of the heating load through the winter. The sunspace also performed well, contributing more than 50% of the load each month. Despite large sunspace temperature variations, the interior temperature never exceeded 75°F (24°C) throughout the winter, showing no tendency to overheat.

L Open stairwell
M Roof vents

Auxiliary heat:
N Fireplace
P Gas forced-air furnace

Thermal buffers:
Q Wind-protected entryway
R North-zoned garage
CONCLUSIONS/FINDINGS

This house receives direct gain from south windows and a clerestory. The central living room has a vaulted ceiling to accommodate the clerestory, which charges an 8-in. (20-cm)-thick brick partition wall. The south glazing includes a small integral sunspace with skylights and a tile floor. Although it is a large house, it is relatively tight, with infiltration at only 0.38 air change per hour under typical winter conditions.

The solar aperture area is only 9% that of the floor area, and, consequently, the passive heating ratio was as low as 15% in December. Because of the efficiency of the building envelope, however, the auxiliary heating energy needs were small for a house of this size. The living room temperature occasionally exceeded 80°F (27°C), due to solar gains from the sunspace and the clerestory.

CONCLUSIONS/FINDINGS

This house is a small split-level design with a partial basement and a crawl space. The south glazing is backed by a 3-ft (1-m)-high brick-veneered concrete wall. The main living area is at grade level, with bedrooms at the half levels above and below.

The auxiliary heating energy is relatively uncertain because the occupants insisted on using their woodstove throughout the heating season. The monthly energy summaries include estimates of wood heat in the auxiliary heating figures. Wood heat is not included in the auxiliary energy plotted on the hourly data graphs, but stove use is obvious from the sudden increases in the indoor temperature at night. The interior temperature was kept relatively cool, averaging 64°F (18°C). This reduced the purchased energy needs and allowed the solar component to meet about half the heating load.

CONCLUSIONS/FINDINGS

This house is a multilevel design with south windows, skylights, and a clerestory. The top level contains the family room, with a vaulted ceiling for the clerestory and a brick-veneered north wall. The living room and kitchen are at grade level and contain the remaining solar glazing. Two bedrooms on the north side are partially below grade level with a half basement.

Although the solar aperture area is relatively small (only 9% of the floor area), it was effective in meeting about half the heating load through the winter. The solar gain had little effect on the north bedrooms, which typically remained as much as 20°F (11°C) cooler than the family room on sunny winter days.

This is a manufactured panelized house with a two-story solarium. The solarium has a tile floor charged by a large direct gain component. Solarium air is open to the interior living space and can be vented into the attic. The solarium glazing is fitted with an R5 insulating curtain that is mechanically drawn at night.
**CONCLUSIONS/FINDINGS**

The house was being used as a sales model, so it was occupied only during the day. Because the building was unoccupied at night, the internal gains were small. The night-time thermostat setting was about 13 °C, which resulted in low average indoor temperatures. The solar component supplied about 60% of the mid-winter heating load.

**Source of Information:** Passive Solar Performance: Summary of 1981-82 Class B Results (by J. Swisher and T. Cowing)
This is a single-story frame house located in central Connecticut. It is constructed on a concrete slab and bermed heavily on the north and west sides, where there are double walls with a 10 in. (25 cm) concrete outer wall and a 4 in. (10 cm) insulated inner wall. The combination of direct gain and a sunspace charges both the slab floor and a brick-faced concrete block wall between the sunspace and the living room. Two sets of sliding glass doors provide some control over heat flows between the sunspace and other zones. Night insulation consists primarily of insulating drapes on the south side. The north and east windows are insulated with sliding panels.
CONCLUSIONS/FINDINGS

The solar components met about 30% of the large heating load, except during a very cloudy December. The occupants kept the doors to the north bedrooms closed. Thus, the solar gain had little effect on these rooms, where the temperature would drop below 60°F (15°C) in the absence of auxiliary heat, even on very sunny winter days.

Performance data for systems evaluation

**PROJECT TITLE**
WEHNER, NOWYSG AND PATTSCHULL
IOWA CITY, IOWA

**BUILDING AND SYSTEM DESCRIPTION**

This two-story house in eastern Iowa receives direct solar gain from 26 square meters of south-facing double-glazed windows. Heat is stored in water tubes directly behind the windows on the second floor. Additional water tubes embedded in the lower-story floor slab convect heat accumulated in the slab up the central dividing wall, to provide heat to the center of the house. Small copper tubes also buried in the south edge of the floor slab provide domestic hot water preheating. The upper floor windows are equipped with RSI-.60 thermal curtains to reduce night-time heat losses.
CONCLUSIONS/FINDINGS

Twenty-two percent of the 27.34 GJ equipment heating load was supplied by the solar system. A solar fraction of 22% was achieved because the occupants were willing to endure very low building temperatures (the temperatures averaged only 15°C for the entire period). There are several reasons for the reduced performance of the system. The house is sited so that it faces 42 degrees west of south, which reduces the available solar energy to, and efficiency of, the collector subsystem. The lack of movable insulation for the lower-level collector glazing is important. Finally, high infiltration levels, which have been calculated as being in excess of 30% of the building heating load, also reduce performance. A large part of the losses appear to be through the uninsulated cooling bed under the floor slab. In spite of above problems, the system did save 5.88 GJ.

The Lo-Cal site is a single detached residence located in Champaign, Illinois. The building is one story built over a crawl space. The energy-saving features include superinsulation (RSI-4.2 walls, RSI-5.8 ceiling and RSI-3.5 crawl-space walls), an airlock-type entry and triple glazing on all of the windows. The floor of the house over the crawl space is uninsulated and the heat loss from the uninsulated ducts in the crawl space is intended to warm the floor for added comfort. The passive system consists of 18.6 square meters of south-facing triple-glazed windows. There is no storage subsystem other than the mass of typical wood-frame construction materials.
The building performed well during the monitoring period, but a major portion of the heat loss was through the uninsulated floor over the crawl space. This loss rate was measured with a co-heating test. The loss rate of the building with the unheated crawl space was 277 W/°K with the crawl space heated. This results in a difference of 145 W/°K, i.e., 53% of the heat loss of the house is through the floor. During normal operation of the building, the heat loss from the uninsulated heating ducts in the crawl space keeps the crawl space at approximately 16.7°C. The loss from the ducts heating the floor was designed to provide warm floors and improve comfort. The performance of this house could be considerably improved if the floor over the crawl space was better insulated and the ducts relocated within the conditioned space or well-sealed and insulated. This improvement would increase the delivered furnace efficiency and reduce the heat loss of the house.

Source of Information: Solar Energy System Performance Evaluation: Lo-Cal
(by Vito, Los. for NEDN)
This two-story masonry house is located in northeastern Massachusetts. It is bermed continuously on the north and west sides and over the roof of the first floor. Direct solar gain is received from south windows and a clerestory above the first floor living room. Insulating drapes were installed in the spring of 1982. The air-source heat pump was operated in the resistance mode only during the monitoring period. A heat exchanger system to regulate the makeup air was not operated during the monitoring period.
CONCLUSIONS/FINDINGS

The house has a relatively low infiltration rate, due to the extensive use of earth berms. However, the heat loss coefficient is relatively high because of the large glazing area. The solar contribution was 34% of the heating load in January but decreased in the spring, probably because of the large overhang above the major direct gain component. The building's ability to retain solar heat was disappointing, as the auxiliary heaters activated soon after sundown on sunny winter days. This should improve with the use of night insulation.

This is a two-story frame house located in north-central Massachusetts. It features a full length sunspace with 208 ft² (19.3 m²) of vertical and sloped glazing. Thermal storage mass is provided by an insulated concrete floor and an 8 in. (20 cm) concrete wall separating the sunspace from the living-dining area. Sliding glass doors and windows in this wall provide the occupants with some control over energy exchanges between interior zones. Also, manually operated windows are located between the sunspace and the second floor bedrooms. Insulating shades are used on the sloped glazing at night.
CONCLUSIONS/FINDINGS

The average interior temperature was maintained at a rather high 70°F (21°C) over the heating season. The living zone temperature was quite stable despite large sunspace temperature swings. The passive solar heating contributions were impressive, providing nearly 50% of the space heating load. Internal energy gains to the living zone appear unusually low for this house. This is due to the location of some major appliances in the unheated basement.

The National Bureau of Standards Passive Solar Test Building was constructed to generate performance data on passive systems and components under highly controlled conditions. The building is divided into four sections by heavily-insulated interior walls. The inside walls, storage mass and glazing can be reconfigured for different test purposes.
CONCLUSIONS/FINDINGS

Cell #1 of the facility is used to house the data acquisition system and a special calorimeter used for testing passive solar components. Data have been taken in the storage wall and direct gain cells as part of the DOE Class A Passive Solar Test Program. In this program, data from highly controlled test periods is used for validation of building energy analysis simulations. Five data sets have been generated to date from the direct gain cell and two from the storage wall cell, each under different ambient or indoor control conditions. These data sets are currently being used by Los Alamos National Laboratory and the Solar Energy Research Institute to do validation runs on DOE2.1, BLAST 2.0, SERI-RES and TRYNSYS. These standard data sets are well-documented and available to other researchers.

Rymark I is a standard bi-level home constructed by Ryan Homes in Frederick, Maryland. It is a 13.4 meter by 11.0 meter rectangular structure fitted with the Ryan standard energy package (RSI-5.3 ceiling, RSI-2.5 wall, double glazing, insulated doors, and foundation perimeter insulation). The rear wall of the house faces south and has 6 square meters of glass. There is no glass on the east or west walls. Rymark I is Ryan's standard building with no modifications other than a southern orientation. This building is used as a "reference" building to compare the performances of Rymark II and Rymark III.
CONCLUSIONS/FINDINGS

This is a conventional "reference" house monitored for side-by-side comparison with Rymark II and Rymark III. The house has a lower heating load than expected because it was kept at an average of 15 °C for the monitoring period. The net solar gain for the season was 8% of the incident solar energy.

Performance data for systems evaluation

**PROJECT TITLE**  
**RYMARK II**  
US/MD-10  
FREDERICK, MARYLAND

**BUILDING AND SYSTEM DESCRIPTION**

Rymark II is the same basic building as Rymark I with some modifications for passive solar. The south-facing window area is almost doubled to approximately 11.5 square meters and the north-facing glass was reduced by 16%. All the windows are triple-glazed and have RSI-.9 "window quilt" movable insulation. A .61 meter overhang is provided on the south side to prevent overheating in the summer.
The net solar gain on the south-facing windows was 735 MJ. The glazing system collected 24% of the incident solar energy. The internal gains were very low because the building was unoccupied.

The floor slab is covered by carpet and participated very little in the net energy balance of the building, maintaining an average temperature of 13.9 °C over the monitoring period. The window insulation was not used regularly during the monitoring period because the building was unoccupied.

The overall savings of this house over the Rymark I house due to the "sun-tempering" of the design is estimated to be 20%, at an incremental cost of $1300.

Rymark III has 17.7 square meters of south-facing glass. The south-facing windows are triple-glazed with reflective louvers behind the inner glazing. The blinds are designed to reflect sunlight onto the brown ceiling which contains a phase-change heat storage system. This system is based on the principles demonstrated in the MIT SOLAR 5 Project. The phase-change ceiling consists of 52 square meters of eutectic salts (sodium sulphate decahydrate) in bags laid between the ceiling rafters. RSI-7 insulation is placed over the bags in the ceiling. The eutectic salts are designed to change phase at 23 °C. The ceiling storage system is located in the southern half of the ceiling in the dining room, kitchen, master bedroom and the recreation room downstairs.
CONCLUSIONS/FINDINGS

Rymark III was unoccupied for the monitoring period. The non-solar energy consumption represents a 23% savings over Rymark I.

The effect of the thermal mass ceiling caused a shift in the auxiliary energy use profile. Typically, the house warmed up slowly in the morning and the auxiliary heat turned off at about 10:00 a.m. The storage system carried the load until 9:00 p.m. when the auxiliary heat came back on.

Source of Information: Solar Energy System Performance Evaluation: Rymark I, II, III (by Vito Labs for NSEP1)
This two-story frame house is located along the lower seacoast of Maine. It is constructed over a full basement and has a retrofit greenhouse built over a crawl space with 161 ft² (15.0 m²) of sloped, south-facing glazing. No significant thermal storage mass is present. A sliding glass door separates the greenhouse from the living room. An electric fan is also used to move heated air from the greenhouse to a first floor bedroom. Insulating shutters are used in the greenhouse only.
CONCLUSIONS/FINDINGS

Space heating requirements were kept to a minimum by maintaining the average interior temperature at a moderate 65°F (18°C) and setting the thermostat back several degrees at night. The greenhouse met 40% of the space heating load. With the sliding glass doors open during the day, heat from the greenhouse was conducted even to areas on the second floor. The lack of thermal storage mass and the closing of the sliding glass door brought the greenhouse temperature down rapidly in the evening, even with the use of night insulation. The temperature in the greenhouse was not permitted to drop below 45°F (7°C).

The Arno Kahn site is located in Hermantown, Minnesota, a suburb of Duluth. The house is a modified direct-gain/sunspace system integrated with a "thermal envelope". The two-story inner zone has approximately 121 square meters of conditioned living space. The outer zone consists of a three-story solarium, a convection loop along the roof, north walls and basement, and the thermal mass below the living zone. The exterior shell is heavily insulated. A sand-filled concrete block three-story mass wall separates the sunspace from the living space. Manually operated shades originally provided night insulation on the south-facing windows. These were replaced by automatically-controlled RSI-1.8 thermal curtains in the fall of 1981.
CONCLUSIONS/FINDINGS

In 1980-81, 27% of the building heat load was lost through the glazing. Subsequently, a complete movable insulation system was installed.

The most notable feature of the house is the "double envelope" design. In theory, air is supposed to flow out the top of the sunspace during the day, across a ceiling chase and down the north walls, dumping the heat into the basement slab and earth below. At night, air is supposed to flow up the north walls, picking up heat from the basement. In practice, this flow was found to be very limited, and the outer envelope temperatures were highly stratified.

(by Vitro Labs for NSDU)
This large two-story house in southeastern Nebraska has a variety of passive solar features. The lower level has a large sunspace with both vertical and sloped glazing. A common wall between the sunspace and the living room is heavily glazed for pass-through direct gain. A thermostatically-controlled sunspace fan charges a rockbed below the brick floor of the sunspace. The upper level receives direct gain through south windows.
CONCLUSIONS/FINDINGS

The auxiliary heating needs were quite low for a building of this size. The solar contribution was small during an unusually cold January but increased to 40% during February and March. The poor January performance can be attributed to two factors. First, the mass wall component was shaded during much of the afternoon. The higher sun angles after January alleviated this problem. Second, the cold January temperatures caused excessive heat losses through the sunspace, negating much of its energy collection. Because the rockbed is below the sunspace, not the living space, its energy storage is of little use to the living space when the sunspace is colder than the living space, as was the case throughout January.

by J. Swisher and T. Cowing
This small slab-on-grade house is located in Black Mountain, in western North Carolina. It has mass walls behind most of the south glazing. These walls are made of 20 cm-thick concrete blocks filled with cement. The south glazing is fitted with insulating shades for reducing both winter night-time heat loss and summer day-time heat gain.
CONCLUSIONS/FINDINGS

The amount of south glass is quite small: it is less than 10% of the floor area of the house. Nevertheless, it was effective in meeting 36% of the heating load through the winter. The thermal mass helped maintain relatively stable temperatures in the living space.

This house is located in a wooded area near Trenton, New Jersey. It incorporates a two-story direct gain sunspace, a three-story Trombe wall and a passive solar water preheat tank. Storage of solar heat is provided in the .30 meter thick Trombe wall and in a series of phase-change rods in the sleeping loft. A small fan redistributes collected heat in the upstairs to the lower floor.
CONCLUSIONS/FINDINGS

The overall collection efficiency was an estimated 18% of the total incident radiation.

The conduction heat loss from the sunspace was as large as the solar energy collected, at 9.12 GJ lost. This loss was due to the large (15.6 net m² glass area. The addition of a movable insulating curtain could reduce the heat loss from the glass area by up to 1/3. This addition would be the single most effective method of increasing the solar heating contribution.

The estimated heat flux from the interior of the Trombe wall was 1.66 GJ over the six-month season, which translates to an estimated overall collection efficiency of 4%. This indicates a fundamental problem at the site—the high exterior losses from the Trombe wall. The site owner operated the wall in a purely conductive mode; that is, the interior wall vents were not opened during the day. Energy was transferred through the wall in a conduction mode only, which may have limited the wall output to some extent.

The Trombe wall had a seasonal variation in temperature as well as a daily temperature swing. The mss wall participates less in the dead of winter (Dec. and Jan.) when the building temperature nearly equals the wall temperature. The wall did provide a net positive effect, since it was essentially adiabatic (i.e., no net heat transfer) during most of the six-month heating season.

Source of Information: Solar Energy System Performance Evaluation: Environmental Partnership
(by Vitro Labs for NSDU)
The collection aperture on this single-story residence in central New York State consists of vertical glazing on most of the south wall and a clerestory which admits solar radiation into the north rooms. The glazing is fixed double-walled fiberglass with operable glass windows to permit venting. All south-facing glazing has movable quilt-type insulated curtains. Both the south wall and the clerestory have overhangs to prevent summer overheating. Heat storage is in the concrete floor slab and exterior insulated concrete walls.
CONCLUSIONS/FINDINGS

The system was operational throughout the 1980-81 heating season and performed very well. The house was unoccupied for the entire period. During this period, the auxiliary heating thermostats were set back. This allowed the solar system to supply most of the space heating requirements of the building. Since the house was unoccupied, there was no one there to operate the movable insulation. It is anticipated that when the house is occupied the increased heating load resulting from the higher thermostat setting will be partially offset by the use of the insulating curtains.

Source of Information: Solar Energy System Performance Evaluation: Gill Harrop
(by Vitro Labs for NEDO)
The lower floor of this 149 square meter, two-level house in Cincinnati, Ohio is below grade. The greenhouse has 37 square meters of double glazing and is constructed so that solar energy can be admitted to both floors. The upper 8 square meter portion of the greenhouse is a site-built active solar collector, from which solar heated air is fan-forced into the living space. Insulating shades (RSI=.6) reduce greenhouse heat losses at night. Additional solar energy is collected by two windows located in the sections of the south wall which extend to the sides of the greenhouse. Thermal storage is provided by a 30 centimeter concrete and brick mass wall, located between the greenhouse and living area, the floor slab of the greenhouse and a phase-change module mounted on the south face of the mass wall. Extra heat, when required, is provided by a wood-burning stove and electric baseboard heaters.
CONCLUSIONS/FINDINGS

The infiltration loss was 36% of the building heat load. The internal gains were high. This is due to the frequent use of the electric clothes dryer which was vented indoors during the heating season. The electric baseboard heaters provided 21% of the heat load. The electric baseboard heaters were mainly used in the bedrooms on the lower level. Because of stratification of heat in the building, the upstairs is always warmer than the downstairs. A ceiling fan is used in the stairwell to try to destratify the air, but its effectiveness is limited. At times, when the greenhouse was hot, the upstairs overheated and the downstairs was cool and required auxiliary heating.

The movable insulation in the greenhouse was used when possible on cold nights and to prevent overheating during warm days. The operation of the "window quilt" was limited for much of the season due to problems with the curtain pulling loose from the track. The weight of the curtain on a 60° slope tends to pull it out of the track.

The storage wall absorbed 19.15 GJ and gave off 19.03 GJ. Ninety-five percent of the solar energy used went through storage before going to the load. The phase-change system responded very quickly to incoming solar radiation. The phase-change storage tubes in the vertical position seem to stratify severely.

This single-story home, located in Eugene, Oregon, has a direct gain system with 16.1 square meters of south wall glazing area and 2.9 square meters of clerestory windows. Eighteen 210-litre drums located directly behind the south wall windows provide thermal storage. Auxiliary storage is provided by the 10 cm floor slab. Night heat losses from the clerestory and the windows directly in front of the water drums are reduced by insulating shutters which have an RSI-2.5 value. Auxiliary space heating is provided by a wood stove and an electric furnace unit.
Performance Summary

Monthly Heating Load

Load Reduction from Passive Solar

Annual Summary

Load Reduction from Internal Heat Generation

Net Auxiliary Heating

Conclusions/Findings

The number of heating degree-days for the monitored period, 4,129, was 8% lower than the long-term average of 4,503 heating degree-days. The amount of measured insulation available to the south glazing was significantly lower (50%) than the long-term expected average. The lower insulation values are partially due to local obstructions, consisting of a house located not too far to the south and a picket fence. In addition, the weather cover on the winch for the shutters shades the low collectors and pyranometer part of the time. The low available insulation levels in part explain the rather poor performance demonstrated by the passive solar system. Also influential were the elevated interior temperatures which required additional auxiliary energy to maintain.

The house was occupied during the entire monitored period. The owners did experience some difficulties operating the movable insulation. The shutters jammed in the partially-open position, which prevented calculation of the operational incident solar energy or night-time R-values of the windows. Losses from the collector are based on estimated times of operation.

Passive and Hybrid Solar Low Energy Buildings

Performance data for systems evaluation

**PROJECT TITLE**

SITE NEL

JAMESTOWN, RHODE ISLAND

**US/RI-02**

**BUILDING AND SYSTEM DESCRIPTION**

This single-story house is located near the Atlantic seacoast in Rhode Island. It was manufactured in sections and assembled on a full-basement concrete foundation. It has a sunspace with 6.5 square meters of sloped glazing and a concrete floor for thermal mass. The house also receives direct solar gain through 9.7 square meters of south glazing. Heated air from the sunspace can be blown to the bedrooms in the rear of the house through insulated plenums in the basement, although the fan did not operate during the monitoring period.
This house remained unoccupied through the heating season so there was very little internal heating. Also, the interior temperatures were allowed to float during December and January and at times fell below 50°F (10°C). Thus, the measured solar contribution to the space heating load of 46% does not reflect the system's performance under normal conditions.

Page 255
Performance data for systems evaluation

**PROJECT TITLE**

**ROBERTS HOME**

**US/VA-01**

**RESTON, VIRGINIA**

**BUILDING AND SYSTEM DESCRIPTION**

Space heating for this house is supplied by three sections of two-story Trombe wall, and a sunspace located on the third floor. Thermal storage is provided by the .30 meter Trombe wall, a hollow-core north wall and two centrally located fireplaces. RSI-2.1 thermal curtains reduce night-time heat losses from the Trombe wall.
The Trombe wall collection efficiency was 32%, while the sunspace collection efficiency was 33%. The movable insulation subsystem required 0.53 GJ to operate. Thus, the solar collection Coefficient of Performance (COP) was 38.0. Ninety-eight percent of the solar energy to the load was delivered via storage. Direct gains were small with the sunspace contributing about 6.94 GJ of the collected solar energy. Most of the sunspace solar energy heated the upper level of the home, while 1.99 GJ were transferred by fans into the rear mass air-core wall. The automated movable insulation system reduced heat losses through the single-glazed Trombe wall.

The performance of the passive solar cooling subsystem was excellent. Auxiliary cooling energy was small, 0.07 GJ, and was used only at the end of July. The storage mass worked very well, reducing temperature swings during the cooling season. A total of 22.30 GJ of thermal energy was removed from the home by a combination of the building's resistance to net radiant gains and through night venting via windows, cool tubes, and the twin thermal chimneys. The thermal chimneys have been shown to remove approximately 24.6 MJ per hour at a 4.4 °C difference in temperature from inside to the outdoors.

Source of Information: Solar Energy System Performance Evaluation: Roberts Home, by Vitro Labs for NSEU
This small slab-on-grade house in northern Virginia has a water wall in the south-facing great room on the lower level. The upper level receives some direct gain. The water wall consists of sixteen 94-gal (355-L) modules made of black fiberglass-reinforced polyester.
CONCLUSIONS/FINDINGS

The solar components performed well, meeting almost half of the heating load. The large thermal mass maintained comfortable temperatures in the great room, with no overheating. The auxiliary heating control used a nighttime setback of the great room temperature and a daytime setback of the bedroom temperatures. Thus, the temperature in the bedrooms often dropped below 60°F (18°C) during cloudy winter days.

Performance data for systems evaluation

PROJECT TITLE
US/VT-02

SITE NED
NEWPORT, VERMONT

BUILDING AND SYSTEM DESCRIPTION

This single-story frame house is located in northern Vermont. It is a simple redesign of a standard "tract" home, with significant energy conservation features such as double-wall construction and triple-glazed windows. No thermal storage mass is provided other than that attributable to the interior structure and furnishings. Ventilation air for the living zone is tempered by an air-to-air heat exchanger.
An effective vapor barrier and extensive insulation contributed to a relatively low building heat loss coefficient of 221 Btu/hr·°F (117 W/°C) and typical infiltration rate of 0.20 air change per hour. The relatively small south glazing area supplied 20% of the space heating load. The solar effects occurred primarily during the daytime with little carryover to nighttime periods. The thermal mass was sufficient for the small glazing area, as the interior temperature was between 65° and 70°F (18° - 21°C) about 80% of the time. Interior partitions apparently prevented solar heating in the northern rooms.

CONCLUSIONS/FINDINGS

Performance data for systems evaluation

PROJECT TITLE
Clairemont House Site MAC
Eau Claire, Wisconsin
US/WI-01

BUILDING AND SYSTEM DESCRIPTION

This house in western Wisconsin receives direct gain from south windows and clerestories which charge interior brick storage walls. A small integral solarium with a concrete floor is adjacent to the living room. The house is well-insulated, with RSI-5.8 walls and triple-glazed windows. South windows have insulating drapes to reduce night-time heat loss.
CONCLUSIONS/FINDINGS

Due to the efficiency of the building envelope, the auxiliary heating needs were low for such a cold climate. The solar component contributed 26% of the winter heating load. Although the solarium temperature fluctuated a great deal, the temperature in the rest of the house was more stable and comfortable.

ABSTRACT

This document presents the results of a survey of monitored passive and hybrid solar low energy residential buildings conducted within IEA countries during the period from autumn 1983 to spring 1985. The survey was undertaken as part of Subtask A, Performance Measurement and Analysis, of Task VIII, Passive and Hybrid Solar Low Energy Buildings of the IEA Solar Heating and Cooling Programme. One of the objectives of this Subtask is to report on the availability of data from monitored passive and hybrid solar low energy residential buildings in the member countries. The major part of the report consists of building description forms which briefly describe the buildings, summarize performance, list available data and identify reference sources for further information. More detailed performance data is provided for 60 of the buildings. To assist the reader in finding projects of particular interest, an indexing system has been generated, using 16 different entries from the forms.

This is a report in a series of reports from

IEA Solar Heating and Cooling Programme
Task VIII : Passive and Hybrid Solar Low Energy Buildings

Document no. 8.5: WD/TR Distribution: Unrestricted
